

In our Software Design project, we chose Supabase because it provides an integrated backend with authentication, database management, and real-time capabilities, which simplified our development process and reduced the need for multiple services. My main contribution focused on implementing Google OAuth authentication. I configured the Google Cloud Console by creating OAuth credentials and setting up authorized redirect URIs, then integrated these with Supabase authentication settings. I used built-in GitHub integration inside supabase to directly link GitHub with our project in supabase. I also created a supabase file using the command "npm install -g supabase" and inside the supabase file there is a migrations file which defines and tracks how your database structure evolves over time. A migration is a version-controlled SQL file that describes changes to your database, such as: Creating tables Updating columns Adding constraints or relationships. I also assisted in testing login flows and troubleshooting issues related to user data not being stored correctly. Through this, I gained practical experience in authentication systems, API configuration, and debugging integration between frontend and backend services in a collaborative development environment. Below is my irrefutable proof or evidence to show my contributions to the project so far.
