

Makubung Tjeding's Individual Sprint Retrospective:

Student number: 2807685

During Sprint 1, my main contribution to the project was implementing the user authentication system for our Campus Marketplace application. I focused on integrating Google OAuth using Supabase, which allows users to securely sign up and sign in using their Google accounts. This involved setting up the Supabase client on the frontend, configuring environment variables, and connecting the authentication flow to both the SignUp and SignIn components. I also ensured that the authentication worked in both local development and the deployed Azure environment by dynamically handling redirect URLs.

One of the more challenging aspects of this sprint was debugging the OAuth flow, particularly resolving issues related to incorrect redirect URIs and Supabase callback configurations. At one point, the authentication failed with a "Unable to exchange external code" error, which required me to carefully review both the Google Cloud Console and Supabase settings. Through this process, I gained a deeper understanding of how third-party authentication flows work and how different systems interact during login.

Another difficulty I encountered was understanding where authentication logic should reside within the system architecture. Initially, I considered integrating the backend into the login process, but I learned that Supabase handles authentication directly from the frontend, with the backend being used only for protected resources and business logic. This helped me better understand modern full-stack architecture and separation of concerns.

If I were to approach this sprint again, I would spend more time upfront planning the authentication flow and documenting configuration steps to avoid repeated debugging. I would also begin implementing protected routes earlier to ensure a smoother integration with the rest of the application.

Overall, my work forms a foundational part of the system, as authentication is required before users can interact with marketplace features. This sets the stage for future development, including user-specific data handling and secure backend communication.
