

Individual Sprint 2 Retrospective – Makubung Tjeding Jacobs - 2807685

During Sprint 2, I primarily worked on implementing the **Listings feature** for the Campus Marketplace system. On the frontend, I developed the Student Dashboard interface using reusable React components such as ListingCard, ListingGrid, and CategoryFilter. I replaced mock data with real data fetched from the backend API and implemented category-based filtering. I also contributed to building the listing details view, allowing users to click on an item and view more information.

On the backend, I helped implement the listings API using Express and Supabase. This included creating endpoints to fetch active listings and create new listings, as well as adding input validation to ensure data consistency. I worked on integrating Supabase PostgreSQL with the backend and ensured that listings were correctly stored and retrieved. I also began working on image upload functionality using Supabase Storage.

One of the main challenges I faced was debugging integration issues between the frontend and backend. Errors such as incorrect API routes, JSON parsing failures, and Supabase relationship conflicts (especially ambiguous foreign key joins) slowed progress. I also struggled with module system issues (CommonJS vs ES Modules) and handling asynchronous data in React. However, resolving these issues improved my understanding of full-stack development.

If I were to approach this sprint differently, I would spend more time planning API structures and database relationships upfront to avoid rework. I would also adopt a stronger test-driven approach earlier in development and improve error handling from the beginning.

My work fits into the overall system as the Listings feature is a core component of the platform. It enables users to create, browse, and interact with items, forming the foundation for future features such as messaging, transactions, and payments.
