

Makubung Tjeding's Individual Sprint 3 Retrospective:
Student number: 2807685

During Sprint 3, my main contribution was building the **Admin Management System** for our UniSquare platform. I worked on the Admin Dashboard, which gives administrators one place to manage the system. The dashboard included sections for summary statistics, facility settings, flagged listings and reviews, analytics, user management, and platform settings. I used React components and a custom hook so that the layout and logic were separated. This made the code cleaner and easier to maintain.

One of the main difficulties I faced this sprint was integrating my work with the rest of the project while keeping the tests passing. After pushing changes, our Jest coverage pipeline showed failures. For example, the AdminDashboard tests failed because the errors object was sometimes undefined, which caused `Object.entries(errors)` to crash. I fixed this by adding safer default values and checks before rendering the error banner. There were also routing-related test errors in StudentDashboard because `useLocation()` was being used without a Router context in the tests. This taught me how important proper test setup is when working with React Router. Another issue happened in ListingActions, where some mocked listing data did not include `listing_type`, which caused test failures. We corrected the mock data and improved validation.

What I found difficult this sprint was balancing new feature development with debugging and improving existing code. Building the dashboard itself was manageable, but making sure it worked correctly with the rest of the system took more time than expected. I learned that integration problems often appear after features are completed, which is why regular testing is important throughout development.

If I could do this sprint again, I would spend more time writing tests earlier instead of waiting until the end. That would have reduced some of the issues we experienced during CI/CD checks. I also learned the importance of defensive programming, especially when handling data from hooks and APIs. Overall, my work fit into the larger system by giving administrators tools to monitor platform activity, manage users, review flagged content, and maintain the marketplace efficiently.
